

E-Blast Cervical Cancer and Pregnancy

Cervical cancer is the fourth most common malignant tumor in women worldwide. This neoplasm is most often associated with high-risk types of Human Papillomavirus (HPV). Although cervical cancer during pregnancy is rare, several factors must be considered when diagnosed, including the stage of the tumor, gestational age, and the potential impact of treatment on pregnancy.

If diagnosed early, the cancer is usually confined to the cervix and may not need immediate treatment. However, if the cancer is at a more advanced stage, treatment will need to be started as soon as possible.

Treatment for cervical cancer can sometimes affect fertility. If you would like to stay pregnant in the future, ask your doctor about options that do not compromise fertility. Cervical cancer diagnosed early can be cured by removing or destroying precancerous or cancerous tissues; therefore, it is essential to have routine tests.
